Lower Limb DVT Ambulatory Emergency Care Pathway
Ambulatory Emergency Care (AEC) Unit

Open: Monday – Friday 9am – 7pm

Consultant: Dr M Oldfield
Consultant: Dr D Harris
Lead Nurse: Catie Paterson

Direct Line: 0771 580 8241
Land Line: 0208 934 3883
Fax: 0208 934 3884

Medical On Call Team
SPR: 174
SHO: 172/173

DVT Service Monday – Friday 9am – 4pm

Patient From
ED (Emergency Department),
AAU (Acute Assessment Unit),
GP

ASSESSMENT

Observations:
T
P
BP
RR
O₂ Sats

Tests:
CxR

Bloods:
U&E
FBC
LFT
CRP
D-Dimer

EXCLUSION CRITERIA
- Unable to attend appointments
- At high risk of bleeding if anticoagulated
- Pregnancy (if over 18/40 weeks gestation refer to obstetrics on call)
- Patient on Warfarin already
- For Upper Limb DVT discuss with vascular surgeon on call

Clinical Probability Assessment (page 3)

DVT Diagnosis (page 5)

DVT Treatment (page 7)

Ambulatory Emergency Care (AEC)

IN HOURS DVT Nurse
09:00-16:00

Ring extension 6416 to confirm AEC capacity
Copy of notes with patient to AEC Clinic

OUT OF HOURS ED
16:00 – 09:00

Request ultrasound scan on CRS
Place notes in DVT slot in A&E reception
### Clinical Probability Assessment

**Hospital number:**

**Date of birth:**

**Name:**

**Address:**

**Postcode:**

**Telephone number:**

**GP name:**

**Practice name:**

**Practice telephone number:**

**Date:**

**Time seen:**

**Seen by – print name:**

**Signature:**

**Position:**

**Allergies:**

---

**T**  |  **P**  |  **R**  |  **BP**  |  **SO on air**  |  **Weight**
--- | --- | --- | --- | --- | ---

### DVT IN PREGNANCY

If less than 18 weeks gestation can be scanned via A&E/MGPU route.

If more than 18 weeks gestation patient must be referred to the Maternity bleep holder – Bleep 552.

---

**Presenting Complaint:**

**History of presenting complaint:**

**Past Medical History:**

---

#### Clinical Probability Assessment Score

**Are there diagnoses present?**

- ☐ Cellulitis
- ☐ Superficial thrombophlebitis
- ☐ Calf trauma or haematoma
- ☐ Ruptured Baker's Cyst
- ☐ Or any other diagnosis

**Are major signs PRESENT on examination?**

- Record whether the following are present: (please tick)
  - ☐ Unilateral calf swelling >3cm
  - ☐ Calf + Thigh both swollen
  - ☐ Tenderness along deep vein

**Is a risk factor PRESENT?**

- Record whether there is a history of the following: (please tick)
  - ☐ Recent major surgery in last 90 days or lower limb trauma
  - ☐ Inpatient stay or procedure in last 90 days
  - ☐ Major medical illness including cancer
  - ☐ Previous proven DVT or PE
  - ☐ Known thrombophilic defect
  - ☐ Recent long haul travel > 4 hours
  - ☐ Recent immobilisation in plaster or in bed >3 days
  - ☐ Pregnancy or post partum (up to 6 weeks)
  - ☐ Use of HRT or oestrogen containing oral contraceptive pill
  - ☐ Strong immediate family history of VTE

**If present score =0 OR NOT PRESENT score =1**

**If one or more are PRESENT score =1**

**OVERALL SCORE = ******

**Interpretation:** Low =0; Intermediate =1; High =2/3

- Is there any evidence for pulmonary embolism? YES / NO
- Is there any evidence for alternative diagnosis to DVT? YES / NO
- Could the leg be ischemic? (consider referral to vascular surgeons) YES / NO
- Are there any symptoms and/or signs suggestive of underlying malignancy? YES / NO

Medication:
DVT Diagnosis

Is patient high or intermediate clinical probability?

Yes

Suspected DVT

Weigh patient

Refer for diagnostic ultrasound next available day

Prescribe dalteparin as per chart (page 8) up to scan

Yes

Does scan confirm DVT?

No

Continue Pathway

Unlikely to be DVT

Discharge to GP with documentation

For follow within 24 hours

If symptoms still unresolved represent to GP/ED

Is D-Dimer positive?

Yes

Unlikely to be DVT

Discharge to GP, No follow up required

No

Was patient high clinical probability?

Yes

Small possibility of DVT

If symptoms worsen or persist patient should represent.

Repeat scan in 1 week

Discontinue dalteparin

No

Plan

Diagnosis / Problems
Ultrasound Report

To be completed by the RADIOLOGIST or ULTRASONOGRAPHER

Doppler ultrasound report:

DVT Ambulatory Care Pathway. Version 3
**DVT Treatment**

**DVT Confirmed as:**

| SAPHENOUS VEIN is a superficial vein  
| This does not require anticoagulation |

**BEWARE SUPERFICIAL FEMORAL VEIN IS A DEEP VEIN THROMBOSIS**

| PROXIMAL DVT | CALF DVT |
| - Common femoral vein  
| - Superficial femoral vein  
| - Deep femoral  
| - Popliteal | - Peroneal vein  
| - Post tibial vein  
| - Anterior tibial vein  
| - Soleal vein  
| - Gastrocnemius vein |

### Weigh the Patient

### Prescribe dalteparin as per chart (page 8) by subcutaneous injection in the first page of yellow book

### Prescribe a loading dose of warfarin in the first page of yellow book *

**IF IVDU OR KNOWN MALIGNANCY DO NOT START WARFARIN, USE LONG TERM LMWH.**

Start the Warfarin therapy so the anticoagulation clinic is on the 4th day. Clinics are held:

Kingston Hospital Monday and Thursday

### Fill out anticoagulation referral form (page 11) and fax to the anticoagulation clinic on 0208 934 3245

### Complete all details in yellow book

### Give patient information sheet with contact numbers

---

* Standard Regime:
  10mg/10mg/5mg on 3 consecutive days.
  Use reduced intensity regime: 10mg/5mg/5mg for patients with one or more risk factors:
  - Age>75
  - Heart Failure
  - Renal failure
  - Weight<55kgs
  - Patient on interacting medicines – see Appendix 1 of the latest British National Formulary (BNF)
Dalteparin (Fragmin) Dosing Guidelines

Dalteparin should be given for a **minimum of 5 days** and continued until the INR is **within** the targeted range (e.g. either 2.0-3.0 or 3.0-4.0)

**Single use, preloaded disposable syringes should be used.**

**Pregnancy**

- Dosage regimen for dalteparin treatment of DVT is 100 units/kg bd, maximum dose is 18,000 units/24 hours.
- When dosing these patients, the **actual pre-pregnancy body weight** is used.
- Monitoring anti-Xa is only required if at extremes of body weight (discuss with a haematologist).
- Inject dalteparin into the thigh, not abdomen.

**Women of childbearing age have urine pregnancy test prior to starting anticoagulation**

**The duration of Anticoagulation varies according to presenting features**

Information for Patients

You have been asked to attend the Ambulatory Care Unit [ACU] at Kingston Hospital for continuing treatment for DVT

A deep vein thrombosis (DVT) is a blood clot in a leg vein. The common cause is immobility. A complication occurs in some cases where part of the blood clot breaks off and travels to the lung (pulmonary embolus). This is usually prevented if you are given anticoagulation treatment.

What is a deep vein thrombosis?

A deep vein thrombosis (DVT) is a blood clot that forms in a deep leg vein. Veins are blood vessels that take blood towards the heart.

Deep leg veins are the larger veins that go through the muscles of the calf and thighs. (They are not the veins that you can see just below the skin.) When you have a DVT the blood flow in the vein is partially or completely blocked, depending on whether the blood clot partially or completely fills the width of the vein.

A calf vein is the common site for a DVT. A thigh vein is less commonly affected. Rarely, other deep veins in the body form blood clots.

Why do blood clots form in leg veins?

Blood normally flows quickly through veins, and does not usually clot. Sometimes a DVT occurs for no apparent reason. However, the following increase the risk of having a DVT:

- **Immobility** which causes blood flow in the veins to be slow. Slow flowing blood is more likely to clot than normal flowing blood.
  - A surgical operation which lasts more than 30 minutes is the most common cause of a DVT. The legs become still when you are under anaesthetic. Blood flow in the leg veins can become very slow.
  - Any illness or injury that causes immobility increases the risk of a DVT.
  - Long journeys by plane, train, etc, are thought to cause a slightly increased risk of DVT. This is probably due to sitting cramped for long periods.

Authors: Sophie O’Brien; Catie Paterson; Dr Matt Oldfield, Alexandra Dunkerley
DVT Ambulatory Care Pathway. Version 3
• **Damage to the inside lining of the vein** increases the risk of a blood clot forming. For example, a DVT may damage the lining of the vein. So, if you have a DVT, then you have a higher than average risk of having another one sometime in the future. Some conditions such as vasculitis (inflammation of the vein wall) and some drugs (for example, some chemotherapy drugs) can damage the vein and increase the risk of having a DVT.

• **Conditions that cause the blood to clot more easily than normal** (thrombophilia) can increase the risk of having a DVT. Some medical conditions can cause the blood to clot more easily than usual. For example, nephrotic syndrome and antiphospholipid syndrome. Some rare inherited conditions can also cause the blood to clot more easily than normal. For example, factor V leiden.

• **The contraceptive pill** and **hormone replacement therapy (HRT)** which contain oestrogen can cause the blood to clot slightly more easily. Women taking 'the pill' or 'HRT' have a small increased risk of DVT.

• **People with cancer or heart failure** have an increased risk of having a DVT.

• **Older people** are more likely to have a DVT, particularly if you have poor mobility or have a serious illness such as cancer.

• **Pregnancy** increases the risk. About 1 in 1000 pregnant women have a DVT.

• **Obesity** also increases the risk of having a DVT.

**How common is a deep vein thrombosis?**

It is estimated that about 1 in 2000 people have a DVT each year in the UK. This ranges from less than 1 in 3000 in people under the age of 40 years to up to 1 in 500 in those over 80 years.

**What are the symptoms of a deep vein thrombosis?**

The typical symptoms are pain, tenderness, and swelling of the calf. Blood that would normally go through the blocked vein is diverted to outer veins. The calf may then become warm and red. Sometimes there are no symptoms and a DVT is only diagnosed if a complication occurs such as a pulmonary embolus (see below).

**Do I need any tests?**

Sometimes it is difficult for a doctor to be sure of the diagnosis from just the symptoms as there are other causes of a painful and swollen calf. For example, a muscle strain or infection. If you have a suspected DVT you will normally be seen urgently at hospital for assessment and tests to confirm or rule out the diagnosis. Two commonly used tests are:

- **The D-dimer test.** This is a blood test that detects fragments of the breakdown products of a blood clot. The higher the level, the more likely that you have a blood clot in a vein.

- **An ultrasound scan of the leg** which can often detect a clot in a vein.

Sometimes these tests are not 100% conclusive and more detailed tests are necessary. For example, **Contrast venography.** In this test a dye is injected into the leg veins. X-ray tests can then detect the dye which shows to be not flowing if a vein is blocked by a clot.
Is a deep vein thrombosis serious?

It can be. When a blood clot forms in a leg vein it usually remains stuck to the vein wall. The symptoms tend to settle gradually. However, there are two main possible complications:

- **Pulmonary embolus** (a blood clot which travels to the lung).
- **Post-thrombotic syndrome** (persistent calf symptoms).

**Pulmonary embolus**

In a small number of people who have a DVT, a part of the blood clot 'breaks off'. This travels in the bloodstream and is called an embolus. An embolus will travel in the bloodstream until it becomes stuck. An embolus that comes from a clot in a leg vein will be carried up the larger leg and body veins to the heart, through the large heart chambers, but will get stuck in a blood vessel going to a lung. This is called a pulmonary embolus.

A small pulmonary embolus may not cause any symptoms. A medium sized pulmonary embolus can cause breathing problems and chest pain. A large pulmonary embolus can cause collapse and sudden death. It is estimated that about 1 in 10 people with a untreated DVT develop a pulmonary embolus large enough to cause symptoms or death.

**Post-thrombotic syndrome**

Without treatment, up to 6 in 10 people who have a DVT develop long-term symptoms in the calf. This is called 'post-thrombotic syndrome'. Symptoms occur because the increased flow and pressure of the diverted blood in other veins can affect the tissues of the calf. Symptoms can range from mild to severe and include: calf pain, discomfort, swelling, and rashes. An ulcer on the skin of the calf may develop in severe cases.

Post-thrombotic syndrome is more likely to occur if the DVT occurs in a thigh vein, or extends up into a thigh vein from a calf vein. It is also more common in people who are overweight, and in those who have had more than one DVT in the same leg.

What is the treatment for a deep vein thrombosis?

The aims of treatment are:

- To prevent the clot spreading up the vein and getting larger. This prevents the possibility of a large embolus breaking off and travelling to the lungs.
- To reduce the risk of post-thrombotic syndrome developing.
- To prevent a further DVT in the future.

**Anticoagulation - preventing the clot from getting larger**

Anticoagulation is often called 'thinning the blood'. However, it does not actually thin the blood. It alters certain chemicals in the blood to stop clots forming so easily. This prevents a DVT from getting larger, and prevents any new clots from forming. Warfarin is the usual anticoagulant. However, it takes a few days for warfarin tablets to work fully. Therefore, heparin injections are often used in the first few days for immediate effect. A serious embolus is rare if you start anticoagulation treatment early after a DVT.

The aim is to get the dose of warfarin just right so the blood will not clot easily, but not too much which may cause bleeding problems. You will need regular blood tests whilst you take warfarin. You need them quite often at first, but then less frequently once the correct dose is found. (If you are pregnant, regular heparin injections rather than warfarin tablets may be used.)
The length of time you will be advised to take anticoagulation for depends on various factors. For example, if you have a DVT during pregnancy or after an operation, then after the birth or when you are fit again the increased risk is much reduced and so the anticoagulation may be only for a few months. On the other hand, some people continue to have an increased risk of having a DVT in which case the anticoagulation may be long-term. Your doctor will advise.

**Compression and raising the leg - to help prevent post-thrombotic syndrome**

If the DVT was in a thigh vein, you may be advised to wear a compression stocking. With this treatment the risk of developing post-thrombotic syndrome is much reduced. You should wear the stocking each day, for at least two years. (Symptoms of post-thrombotic syndrome may develop even several months or years after having a DVT, which is why you should wear the stocking long-term.)

The slight pressure from the stocking helps to prevent fluid seeping into the calf tissues from the outer veins which carry the extra diverted blood following a DVT. The stocking also reduces, and may prevent, calf swelling. This in turn reduces discomfort and the risk of skin ulcers forming.

If you are advised to wear a compression stocking, you should put it on each day whilst lying in bed before getting up. Wear it for the whole day until you go to bed, or until you rest in the evening with the leg raised. Take the stocking off before going to bed.

In addition, you may also be advised to do the following.

- Raise your leg when you are resting. This too reduces the pressure in the calf veins, and helps to prevent blood and fluid from 'pooling' in the calves. 'Raised' means that your foot is higher than your hip so gravity helps with blood flow returning from the calf. The easiest way to raise your leg is to recline on a sofa with your leg up on a cushion.
- Raise the foot of the bed a few inches if it is comfortable to sleep like this. This is so your foot and calf are slightly higher than your hip when you are asleep.

**Preventing a first DVT - or a recurrence of a DVT**

A DVT is often a 'one-off' event after a major operation. However, some people have an ongoing risk of a further DVT. For example, if you have a blood clotting problem, or continued immobility. As mentioned above, you may be advised to take anticoagulation (usually with warfarin) long-term.

Other things that may help to prevent a first or recurrent DVT include the following.

- If possible, avoid long periods of immobility such as sitting in a chair for many hours. If you are able, get up and walk around now and then. A daily brisk walk for 30-60 minutes is even better if you can do this. The aim is to stop the blood 'pooling', and to get the circulation in the legs moving. Regular exercise of the calf muscles also helps. You can do some calf exercises even when you are sitting.
- Major surgical operations are known to be a risk for a DVT - particularly operations to the hip, lower abdomen, and leg. You may be given an anticoagulant such as a heparin injection just before having an operation to help prevent a DVT. An inflatable sleeve connected to a pump to compress the legs during a long operation may also be used. It is also common practice to get you up and walking as soon as possible after an operation.
- When you travel on long plane journeys, train journeys, etc, you should have little walks up and down the aisle every now and then. Also, exercise your calf muscles every now and then whilst sitting in your seat. A separate leaflet called 'Preventing DVT When You Travel' gives more details.
Other treatments

Sometimes other treatments may be considered. For example:

- Thrombolytic therapy (often called 'clot busting') with drugs such as streptokinase or urokinase. These drugs may help to 'dissolve' a blood clot. This is not routine treatment as it is not clear how effective it is. However, it is sometimes used in people with a severe DVT or with a large pulmonary embolus.
- Sometimes an operation is done to remove a blood clot from the leg vein or pulmonary artery. These operations are not routine and it is not clear if they are an effective treatment in most cases.
- Occasionally, an operation is done to place a 'filter' in the large vein above the blocked leg vein. The aim is to stop any blood clots from traveling up to the lungs. This may be considered if anticoagulation cannot be given (for various reasons) or if anticoagulation fails to prevent clots breaking off and traveling up into the larger veins and up to the lungs.

In Summary

- The main cause of DVT is immobility - especially during surgery.
- The most serious complication of DVT is a pulmonary embolus where part of the blood clot breaks off and travels to the lung.
- Persistent calf symptoms may occur after a DVT.
- With treatment, the risk of the above two complications is much reduced.
- Treatment includes anticoagulation, compression stockings, leg elevation, and keeping active.
- Prevention is important if you have an increased risk of DVT. For example, during long operations or when you travel on long journeys.
Ambulatory Emergency Care Unit: Information for Patients and Carers

What is Ambulatory Emergency Care?

Kingston Hospital Trust Ambulatory Emergency Care (AEC) Unit delivers a range of treatments which have historically been administered within the in-patient setting i.e. with you sitting in a hospital bed on a ward. However, evidence and experience has shown that for certain carefully selected conditions it is just as safe and the treatment is just as effective when given as an outpatient. Many people also prefer to have their treatment whilst staying in their own home.

Eligible patients receive their care in the AEC area situated on level 3 of the Surgical Unit and visit the unit on a daily basis during the course of treatment. Of course if you do require hospital admission during your treatment beds are available 24 hours a day on our associated wards.

What advantages does Ambulatory Emergency Care offer me?

You will receive the same treatment as on the ward except that it is scheduled between the hours of 9am and 7pm. This allows you to continue daily life at home.

You will continue to have 24 hours access to Medical and Nursing care despite not staying in a hospital ward. You will be given contact numbers telling you how to contact us throughout your treatment period.

Is Ambulatory Emergency Care right for me?

As you will be required to take a more active role in your care, it is important to find out whether Ambulatory Emergency Care is suitable for you. Your nurse or doctor will discuss this with you.

What can I expect?

You will be assessed and treated by an advanced nurse practitioner who has extensive experience in working with patients receiving treatments in ambulatory emergency care.

The unit is open 5 days a week: Monday to Friday – 8am to 8pm. Outside of these hours you continue to have access to medical support through contacts in the Accident and Emergency department. Of course the usual ways to access medical advice e.g. NHS direct and your GP will also still be able to advise you in an emergency.

What to expect in the Ambulatory Emergency Care Unit:

- You will be seen and assessed. Your AEC nurse will take your temperature, pulse, blood pressure and weight.

- Blood tests and other necessary investigations will be carried out

- You will receive your prescribed treatment, any additional investigations and consequent treatment.

  *Treatments may sometimes run later than expected, you should allow some flexibility for this.*

- The details of the condition you are being treated for and what happens now will be given to you in writing along with contact numbers and details of any appointments.

- If you require hospital admission this will be arranged for you by the AEC nurse who will accompany you to the ward

- If you have any concerns or questions please don’t hesitate to ask-we are here to help!
Dear Patient,

The doctor suspects that you have had a deep vein thrombosis and, until you have a scan, you will be treated with daily injections of dalteparin (Fragmin). This will prevent any clot from enlarging.

- To arrange a scan, please phone the ultrasound department in the Rowan Bentall Wing at Kingston Hospital between 9am and 10am on the next working day. Have this letter to hand when you phone and enter the details of your appointment below.

Telephone Number 020 8546 7711 extension 2824

- At the weekend, the next available scan will be on a Monday so continue to give your own injection of dalteparin (Fragmin).
- Bring this letter with you to the Accident and Emergency department only if you feel unwell.
